TITLE

DEVICE AND METHOD
FOR SEALING PUNCTURE WOUNDS

lms > 5

~~This is a continuation-in-part application of
application Serial No. 7/634,478 filed December 27, 1990.~~

10

BACKGROUND OF THE INVENTION

Field of the Invention

15 The present invention relates to a method for sealing a
puncture wound in a blood vessel and a device for
practicing said method.

Related Background

20 In certain medical procedures, such as cardiac
catheterization, dilatation and counterpulsation, a
catheter or other device is inserted into an artery,
most commonly by percutaneous methods, and then fed
through the arterial tree to the site where needed,
25 frequently, the region of the heart. The site usually
selected for insertion is the groin, because the
femoral artery in that region is relatively easy to
locate.

These procedures are normally initiated by insertion of an angiographic needle, followed by passing a guide wire through that needle into the artery. The needle is then removed leaving the guide wire in place. Next, a sheath-dilator set is passed over the guide wire into the artery in order to enlarge the opening sufficiently to permit entry of the catheter or other device. The dilator is then removed, leaving the sheath or guide 5 cannula in place. The catheter or other device can then be inserted through the cannula with full confidence that when it emerges from the distal end it will be within the lumen of the artery.

10 It should be understood that the subject invention is independent of the nature of the medical device being used to treat the patient. Accordingly, the term "catheter" will be used here in a very generic and broad way to include not only "catheters" in the strict 15 sense, but any device that is inserted into a blood vessel of the body.

Similarly, the subject invention is independent of the blood vessel involved. While it is anticipated that 20 the femoral artery will be the most commonly used blood vessel, other arteries as well as veins might just as easily be involved.

After a procedure, for example, counterpulsation, has 25 been completed, the sheath must be removed and the wound closed. Often, this can be accomplished simply by the application of digital pressure, generally augmented by the use of a pressure dressing. Customarily, pressure must be applied for at least $\frac{1}{2}$ 30 hour, and frequently for much longer than that. While pressure dressings often suffice, it is not uncommon for additional devices, such as sandbags, to be needed. In addition, during this period the patient must be

immobilized, lest movement interfere with the closing process. Because of the pressure required, the time during which it must be applied and the need for immobilization, the procedure is painful and
5 uncomfortable. It also requires prolonged personal attention of a health care professional. Finally, wound closures accomplished in this manner are prone to reopen unexpectedly long after closure appears to have been completed. Patients are therefore often required
10 to remain in the hospital for 24 hours or longer.

Because sealing can be such a problem, cardiologists tend to use the smallest calibre catheters when performing catheterization procedures. Larger calibre
15 catheters, however, are far preferable. An improved sealing procedure whereby larger catheters can be used without increasing the sealing difficulties would greatly facilitate cardiac catheterization.

20 A series of related devices which were designed to address some of these problems is described in U.S. patents Nos. 4,744,364, 4,852,568 and 4,890,612. These three patents describe a mushroom or umbrella shaped device which is used to seal the artery from the
25 inside. The head of the device is placed within the arterial lumen and means are provided to pull and hold the underside of the head against the inside wall of the lumen. It is believed, however, that sealing from the inside can be the source of its own problems,
30 including the promotion of clot formation inside the vessel.

Another method for sealing a puncture wound is described in U.S.P. 4,929,246. The approach taken
35 there is to insert a balloon-tipped catheter into the tissue wound, inflate the balloon against the hole in

the artery and then use a laser to thermally weld the wound closed.

The present invention is believed to overcome most of
5 the drawbacks of the traditional method, without
creating any new difficulties. This is accomplished by
using a plug, preferably a collagen plug or plug of
some other resorbable material, to seal the artery
along its outside wall.

10

SUMMARY OF THE INVENTION

In its most simplified form, the instant invention
involves the placing of hemostatic material against the
15 outside wall of a punctured artery. The hemostatic
material covers the entire puncture site and a
hemostatic seal is formed so as to stop bleeding from
the puncture wound.

20 In one embodiment, the subject invention teaches the
use of a plug, preferably of fibrous collagen material.
The plug is inserted into the tissue wound and is held
against the outside of the artery wall so as to overlap
the puncture wound. Before plug insertion, the artery
25 is preferably clamped by the use of external digital
pressure, at a point slightly upstream of the wound
site. After the plug has been inserted, the upstream
clamping pressure is maintained for a very short period
of time, and then gently removed. Slight pressure may
30 be maintained on the plug to hold it against the artery
wall until a good seal has been established.

In order to insert the plug in accordance with the
procedure outlined above, a special device has been
35 designed. It is comprised of two basic components, a
sheath and a plug pusher or piston. The sheath is
inserted through the tissue until its leading end is

near to or abuts the outer wall of the artery. Thereafter, the plug is advanced through the sheath by use of the plug pusher until the plug abuts the artery wall and overlaps the arterial puncture on all sides.

5 Finally, after a good seal has been established, the sheath and pusher are removed.

BRIEF DESCRIPTION OF THE DRAWING

10 FIG. 1 is an exploded view of one embodiment of an insertion apparatus in accordance with the instant invention.

15 FIG. 2 depicts, in cross section, one embodiment of an insertion apparatus in accordance with the instant invention.

20 FIG. 3 depicts, in cross section, a second embodiment of an insertion device in accordance with the instant invention.

25 FIG. 4 depicts, in cross section, an exploded view of a third embodiment of an insertion apparatus in accordance with the instant invention.

30 FIG. 5 is an enlarged, schematic drawing, in cross section, of an insertion site, showing a balloon catheter, having passed over a guide wire through a guide cannula into the femoral artery of a patient.

35 FIG. 6 shows the insertion site of Fig. 5 after the catheter and cannula have been removed.

FIG. 7 shows the insertion site of Fig. 6 after insertion of a tissue dilator in accordance with the instant invention.

FIG. 8 shows the insertion site of Fig. 7 after insertion of a sheath over the tissue dilator in accordance with the instant invention.

5 FIG. 9 shows the insertion site of Fig. 8 after removal of the tissue dilator and guide wire and after partial insertion of a hemostatic plug and plug pusher.

FIG. 10 shows the insertion site of Fig. 9 after the
10 hemostatic plug has been pushed out of the sheath and while it is being held in intimate contact with the arterial puncture.

FIG. 11 shows an alternative embodiment of the instant
15 invention wherein a collagen balloon is used to seal an arterial puncture.

FIGS. 12a, b, c, d and e show alternative forms of plug which are useful in practicing the instant invention.

20 FIGS. 13 through 23 show the steps of an alternate procedure for practicing the instant invention.

DETAILED DESCRIPTION

25 In certain procedures, for example, intra-aortic balloon pumping ("IABP"), percutaneous transluminal coronary angioplasty ("PTCA") and angiography, as best seen in Fig. 5, a catheter or other device 7 is
30 inserted, often over a guide wire 15, through a guide cannula 3 into an artery 11, most frequently, the common femoral artery in the groin area of the patient's leg 1. When the procedure (e.g., counterpulsation) has been completed, the device (e.g.,
35 the catheter), the guide wire and the guide cannula must be removed and the wound closed.

In accordance with one embodiment of the instant invention, wounds of this type are closed by inserting a plug 57 into tissue wound or channel 9, and holding it against the outside of the artery wall over arterial 5 puncture 13 for a short period of time until a good self-sustaining hemostatic seal is established. Although punctures of the sort made by percutaneous procedures will generally, after removal of all cannulas and catheters, be in the nature of slits, for 10 ease of understanding, they are depicted in the drawings herein more as holes. The shape of the puncture, however, is not critical.

the
B In order to insert ^{the} plug 57, to assure that it is 15 properly located and to be able to hold it in place until a good seal is established, a special insertion apparatus has been designed. One embodiment (Fig. 1) of an insertion apparatus according to the instant invention is comprised of a sheath assembly 23, a plug 20 holder 29 and a plug pusher 33. Sheath assembly 23, in turn, is comprised of an elongated tubular sheath 45 and a collar 35. At its rear end, collar 35 is B provided with ^{an} ~~an~~ external thread 37. In addition, 25 sheath assembly 23 is provided with a sheath channel 27, which runs through the entire assembly, from front end 25, through sheath 45 and through collar 35.

Plug holder 29 is comprised of an elongated rear tubular portion 47 and a coupling 39 which has an 30 internal thread 41. Plug holder 29 also has a channel 31 running throughout its entire length. Coupling thread 41 is designed to mate with collar thread 37 so that when collar 35 is screwed into coupling 39, channels 31 and 27, which preferably are of the same 35 cross sectional size and configuration, are aligned.

Like the other two components, the plug pusher 33 is also comprised of two parts, an elongated piston 49, and a stop knob 43. Piston 49 has a cross sectional size and configuration so as to permit sliding passage 5 into channels 31 and 27 with only minimal clearance. The length of piston 49 is such that when sheath assembly 23 and plug holder 29 are screwed tightly together, shoulder 51 of knob 43 will abut rear end 53 of plug holder 29 as front end 55 of piston 49 is 10 aligned with front end 25 of sheath 45.

It should be noted that pusher 33 is provided with its own channel 19. This is to permit passage therethrough of a guide wire and hence to enable pusher 33 to serve 15 dual functions, as a tissue dilator and as a plug pusher.

In accordance with the method of the instant invention, first the device 7 (e.g., the IAB) and the guide 20 cannula 3 are removed, leaving the guide wire 15 in place (as seen in Fig. 6). If no guide wire has been employed, prior to removal of the catheter and cannula, a guide wire may be inserted. As the cannula is withdrawn, in order to prevent bleeding, the artery is 25 clamped, usually by pressing a finger 2 over the femoral artery upstream of the wound site. Because of this clamping, there is no significant blood pressure inside the artery at the site of the puncture (other than some small retrograde pressure) and the artery 30 tends to collapse.

Although it is believed preferable to employ a guide wire, it is possible to practice the invention without one. It is also possible to practice the instant 35 invention by eliminating the dilator, but this too is not the preferred approach.

The artery is clamped at least in part to prevent tissue channel 9 from filling with a pool of blood. When loose fibrous collagen encounters a pool of blood it tends to disintegrate almost immediately.

- 5 Obviously, once disintegrated it cannot function properly to seal the arterial puncture. Hence, when collagen in loose fibrous form is employed, clamping of the artery is important. It is less important, but still generally advantageous, if the loose fibrous
- 10 material has been tamped down or otherwise compressed. As used herein, the term "loose" includes material which has been compressed or tamped down.

- 15 Collagen that is more densely packed does not disintegrate upon encountering blood nearly as quickly as loose fibrous collagen. Therefore, clamping of the artery is not nearly as important when the hemostatic material is in the form of a densely packed material, as it is when a loose fleece-type hemostatic material
- 20 is employed. Thus, although clamping is believed to be desireable, it is not, in all cases essential.

While the artery remains clamped, the proximal end of ~~B~~guide wire 15 is fed through channel ~~20~~ ¹⁷ of tissue dilator 17. The physician can then slide the dilator down along the guide wire into tissue channel 9 until it reaches the wall of artery 11 (as depicted in Fig. 7).

- 30 The size and shape of the tissue dilator are such as to ensure that the body thereof will not enter the artery. In terms of size, preferably a dilator is selected which is significantly larger than the original guide cannula 3. With respect to its shape, unlike more
- 35 traditional dilators which often have long tapered forward ends, the tissue dilator 17 of the instant invention has a blunt forward end 21. Although end 21

may be slightly rounded or chamfered in order to facilitate smooth passage through tissue channel 9, it is preferable not to reduce it in size sufficiently to permit entry through the arterial puncture 13 into the 5 lumen of the artery.

As noted above, during this phase of the procedure, there is no significant blood pressure in the region of artery 11 adjacent puncture 13. As a result, when end 10 21 of dilator 17 reaches artery 11, the wall of the artery tends to collapse further (as depicted in Fig. 7). The physician knows that the dilator has reached the artery because a noticeable increase in resistance is felt.

15

According to the procedure of the instant invention, once increased resistance is encountered, axial pressure is maintained so as to hold end 21 of dilator 17 against artery 11. Next, a sheath 45 is passed over 20 dilator 17 and advanced along the dilator again until increased resistance is encountered. As with the dilator, increased resistance indicates that front end 25 is against artery 11 (as depicted in Fig. 8). In addition, a marker can be placed around the 25 circumference of the dilator to signal when the distal end of the sheath is aligned with the distal end of the dilator.

Because end 25 of sheath 45 is larger than arterial 30 puncture 9, the sheath cannot enter the arterial puncture. Although the precise dimensions of dilator 17 and sheath 45 are not critical, it is believed desirable that the sheath 45 be 30% to 50% or more 35 larger than the previously removed guide cannula 3. In clinical trials done to date, when the guide cannula was 9 Fr., a 13 Fr. tissue dilator and a 14 Fr. sheath were used. It should be understood, however, that

cannulae which are oversized by as little as 10% may also be suitable.

Once the guide or procedure cannula has been removed,
5 tissue channel 9 tends to collapse. Also, once the procedure cannula and the procedure catheter have been removed, arterial puncture 13 has a tendency to close up. It may therefore be possible or even preferable to use a sheath that is the same size as or even smaller
10 than the previously removed procedure cannula.

With the front end 25 of sheath 45 held snugly against the wall of artery 11, plug 57 is slid down through lumen 27 of sheath 45 (as shown in Fig. 9) until it
15 reaches end 25 of sheath 45 where it encounters artery 11. If an insertion apparatus like that shown in Fig. 1 is used, plug 57 is initially housed in plug holder 29. When it is time for plug insertion, holder 29 is screwed onto sheath assembly 23 by means of threads 37
20 and 41, and piston 49 is inserted into channel 31. Advancement of the piston then forces plug 57 from holder 29 into sheath 45 and through lumen 27 to the artery wall.

25 Once resistance is felt, the physician slowly withdraws the sheath while continuing to maintain pressure against the piston so that plug 57 remains pressed against artery 11. When shoulder 51 of knob 43 abuts rear end 53 of holder 29, the physician knows that plug
30 57 has been pushed entirely out of lumen 27 (as shown in Fig. 10). Axial pressure is maintained for a short period of time, perhaps as little as one minute or as long as five minutes, depending upon the circumstances, to allow plug 57 to seat in tissue channel 9 and
35 against arterial puncture 13. Minimal axial pressure is thereafter continued while clamping pressure is slowly released until a good self-sustaining hemostatic

seal has been confirmed. The sheath, holder, and pusher can all then be removed.

While it is believed that the preferable procedure is
5 to permit both piston and sheath to remain in place
until a self-sustaining hemostatic seal has been
achieved, this is not absolutely necessary. Some
physicians may prefer, once the pressure of the plug
against the artery wall has produced hemostasis, to
10 withdraw the sheath so that the tissue wound may begin
to close down, while maintaining pressure on the plug
by use of the piston alone. Alternatively, the piston
might be withdrawn and reliance placed upon the outer
15 rim of the sheath to hold the plug against the artery
wall and assure hemostasis in that manner.

In addition, removal of the piston without removal of
the sheath permits insertion of a second plug. This
might be necessary where the first plug, perhaps of a
20 loose fibrous material, disintegrates upon encountering
a pool of blood. A second plug, this one of more
densely packed material having greater physical
integrity and less of a tendency toward immediate
disintegration, is inserted in the sheath and the
25 piston reinserted behind it.

An apparatus similar to that of Fig. 1 is depicted in
Fig. 4. The primary difference between the two is that
the plug pusher of the Fig. 4 embodiment does not serve
30 a dual function. Instead, the embodiment of Fig. 4 has
~~8~~ a separate tissue dilator 17 with channel ²⁰~~19~~ running
throughout its length.

Another, somewhat different embodiment of an apparatus
35 for inserting a plug in accordance with the instant
invention is depicted in Fig. 2. The insertion
apparatus 59 of that embodiment is made in the form of

a Y, with a common or sheath leg 61, a plug leg 63 and a dilator leg 65.

In one method of using the apparatus of Fig. 2, tissue
5 dilator 17 and insertion apparatus 59 are preassembled
by passing the dilator through legs 65 and 61 until
enough of dilator 17 extends beyond the forward end of
leg 61 to assure that end 21 will abut artery 11 before
B front end 26 of leg 61 reaches the surface of the
10 patient's leg. The proximal end of the guide wire is
B then fed through dilator channel 39 and the dilator is
slid down the guide wire into tissue wound 9 until end
21 of dilator 17 reaches the wall of artery 11. While
holding the dilator against the artery wall, the
15 physician slides insertion apparatus 59 along dilator
B 17 until end 26 of leg 61 reaches artery 11.

B With end 26 held snugly against artery 11, dilator 17
is withdrawn, but only far enough so as to uncover
20 channel 67 of plug leg 63. Plug pusher 69 is then
moved down through channel 67 until plug 57 has entered
common leg 61 and pusher 69 is then withdrawn so that
it will not interfere with dilator 17 as it passes from
leg 65 into leg 61.

25 Once plug 57 has entered leg 61 and pusher 69 has been
retracted, dilator 17 is again advanced into leg 61.
When resistance is encountered, the physician knows
that plug 57 has reached the artery. While maintaining
30 axial pressure on dilator 17, apparatus 59 is slowly
withdrawn until proximal end 73 of leg 65 reaches
indicator mark 71. The distance between indicator 71
and dilator end 21 is the same as the distance between
B proximal end 73 and forward end 26. Therefore, the
35 physician knows that when mark 71 reaches end 73, all
B of plug 57 has exited from end 26 of leg 61. As was
described in connection with the embodiment of Fig. 1,

pressure is then maintained until a good self-sustaining hemostatic seal has been established.

The embodiment of Fig. 3 is very similar to that of Fig. 1, except that the dilator and plug legs have been transposed. In the Fig. 3 embodiment, plug leg 27 is coaxial with common leg 61 and dilator leg 75 is at an angle, whereas in the Fig. 2 embodiment the reverse is true.

10

Although it is believed that the preferred method for using the embodiment of Fig. 2 is to preassemble dilator 17 in apparatus 59, that is by no means necessary. If the physician prefers, he can just as well insert dilator 17 into tissue channel 9 as was described above in connection with the embodiment of Fig. 1. He can then pass leg 61 over it. With the embodiment of Figs. 4 and 1, while it is believed preferable to insert dilator 17 first, the physician, if he prefers, can preassemble the dilator in the sheath before passing the dilator over the guide wire.

While plug 57 may be made of any resorbable material, collagen is believed to be most suitable. The physical form of the plug may vary widely, with the one selected by the physician being dependent upon the circumstances of the case. For example, where the puncture wound is relatively small and the patient has not been on high doses of anticoagulant and heparin, a plug, like that depicted in Figure 12a, of loose fibrous material, somewhat like fleece or absorbent cotton or oxygenated cellulose, would serve quite well. Alternatively, for larger wounds in patients who have been on anticoagulants and heparin, it may be necessary that the plug be able to maintain some structural integrity for a longer period of time. Under those

circumstances, a plug of more densely packed material, as depicted in Figure 12b, might be preferred.

A third embodiment of a suitable plug is depicted in 5 Figure 12c. In that embodiment, the front end 77 of the plug might be of loose fibrous material, like that depicted in Figure 12a, whereas the remainder 79 could be made of a more densely packed material.

- 10 Yet another type of plug is shown in Figure 12d. In this configuration, the front end 81 is a collagen membrane and the remainder 83 is an expandable collagen sponge.
- 15 It is believed that when a collagen sponge or a densely packed collagen material are employed, very little if any pressure need be applied after the initial seating of the plug. This is believed to be true because the physical characteristics of the sponge-like or densely 20 packed plug and the expansion thereof, as well as its interaction with body fluids in the tissue channel will be adequate to hold the front end against the artery wall.
- 25 It is also believed that, initially, when the plug is pressed against the artery, hemostasis is achieved by mechanical means, i.e., by application of mechanical pressure all around the arterial puncture. Shortly 30 thereafter, however, the hemostatic material begins to bind to the arterial tissue and biochemical hemostasis takes over. Once biochemical hemostasis becomes sufficiently strong to withstand the normal blood pressure within the artery, and therefore self-sustaining, external mechanical pressure can be 35 removed.

Figure 12e shows yet another form of plug, similar to the plug of Figure 12d, but with a lumen 85. This form of plug is designed for use by physicians who prefer not to remove the guide wire immediately after a 5 procedure. The proximal end of the guide wire 15 can be fed through lumen 85 and through the collagen membrane 81. The plug is slid down along the guide wire through tissue channel 9 until its front end reaches the wall of the femoral artery. Indeed, the 10 plug of Figure 12e could even be inserted without the use of a sheath. When the wire 15 is withdrawn, the collagen membrane automatically reseals itself.

As noted earlier, the sheath is substantially larger in 15 cross section than is arterial puncture 13. Consequently, when plug 57, which fills the entire cross section of the sheath channel, reaches the artery, even in its compressed state it overlaps puncture 13 on all sides. Obviously, then, when it 20 exits the sheath and is permitted to expand, a full bandage-like covering over puncture 13 is assured.

In practice it has been found that when using a collagen plug in accordance with the subject invention, 25 a good hemostatic seal can be achieved in five minutes or less. With larger wounds, for example, ones left after removal of 14 Fr. or larger catheters, or after the use of anticoagulants and heparin, sealing may take somewhat longer.

30

Figure 11 depicts another means for practicing the ~~b~~ instant invention. In this embodiment a piston ¹⁸ pushes ahead of its front end a closed balloon 87 formed of a collagen membrane and only partially filled 35 with a collagen substance and a saline solution. The ~~b~~piston ¹⁸ has an injection needle ¹⁸⁹ on its front end which pierces the balloon during the pushing action.

After the balloon 87 exits from the sheath 23 and is pressed against the wall of the artery 11, an inflation fluid is injected via the needle ^{18a} ~~17a~~ to fill and expand the balloon, as shown in Fig. 11, so that the balloon 5 covers the arterial puncture 13 and fills the region of tissue channel 9 immediately adjacent the arterial ~~B~~ puncture 13. The piston ¹⁶ ~~17~~ is thereafter retracted to ~~B~~ withdraw the injection needle ^{18a} ~~17a~~ from the balloon 87. The membrane which forms the balloon 87 then 10 automatically reseals itself to hold the balloon in the inflated condition shown in Fig. 11. The sheath 23 and ~~B~~ piston ¹⁶ ~~17~~ may then be withdrawn. When using this embodiment, the inflation fluid itself should be resorbable, preferably a saline solution or saline 15 mixed with collagen in solution.

As noted above, when the procedure cannula is removed, both the arterial puncture 13 and the tissue channel 9 tend to close up somewhat. The method depicted in 20 Figure 13 through 22 is designed to take advantage of this tendency. In the Figures 13-22 method, neither the hemostasis sheath 45 nor the dilator 17 are pushed through channel 9 all the way to arterial puncture 13. Instead, as shown at 89 in Figures 14, 14A, 15 and 15A 25 they are inserted no further than to within about 3/4 cm. of the artery.

First, digital pressure (see arrows 105 in Figures 13-21) is applied upstream of the wound so as to close 30 down the artery (see arrows 106). In this way the pressure in the artery at the puncture site 13 is no more than about atmospheric pressure. Although the method of this invention could be practiced without applying digital pressure, that would likely result in 35 more profuse bleeding.

Then, as shown in Figure 13, the dilator 17 is inserted over guide wire 15 to about 3/4 cm from puncture 13. It will generally be inserted so that between about 3 and about 6 cm. of its length is beneath the surface of 5 the skin.

One method for assuring that the sheath is inserted to the proper depth is as follows. Once the artery 107 has been punctured and the guide wire is in place, a 10 needle clamp 108, as is depicted in Figure 23, is placed on the needle 109 at the skin line 110. With the clamp in place, the needle is removed from the patient. The needle can then be placed along side the sheath and a mark made on the sheath to indicate the 15 distance from needle tip to needle clamp.

Alternatively, a mark can be made 1/2 or 3/4 cm. closer to the distal end of the sheath. As yet another alternative, a kit can be provided of variable length sheaths, each having a hub at one end, and from that 20 kit a sheath of the proper length, i.e., one having a total length, from hub to distal end, of 1/2 or 3/4 cm. less than the distance from needle tip to needle clamp can be selected.

25 Next, as is best seen in Figure 14, the sheath 45 is slid down over the dilator, again stopping when its distal tip is about 3/4 cm. from the arterial puncture 13. The sheath and dilator can be inserted separately, i.e., in two steps, or together as a unit, in one step.

30

As can be seen in Figures 14a and 15a, the partially collapsed section of tissue channel 9 which is immediately adjacent puncture 13 is not reexpanded. Instead, it remains undisturbed.

35

The next step is to withdraw dilator 17 (as is indicated by arrow A on Figure 15) with guide wire 15

(see Figure 15), leaving only sheath 45 in tissue channel 9. As depicted in Figure 16, a preloaded holder or cartridge 91 with plug 93 therein is inserted (see arrow B) into sheath chamber 97. As cartridge 91 is fully seated within chamber 97, a plunger 95 is used to push (see arrow C) plug 93 into and through sheath 45 until the plug exits the sheath so as to cover puncture 13 and fill that section of channel 9 which is adjacent puncture 13 (see Figures 17 and 17a).

10 *B* Simultaneously, sheath ⁴⁵~~17~~ is slightly withdrawn (indicated by arrows D on Figure 17) to permit plug 93 to be fully discharged from the sheath.

B Plunger 95 is then withdrawn, leaving sheath ⁴⁵~~17~~ to maintain pressure on plug 93. Sheath ⁴⁵~~17~~ can then be used to hold plug 93 in place over puncture 13 until self sustaining hemostasis has been achieved. Alternatively, as depicted in Figure 18, a second preloaded holder or cartridge 99 can then be inserted 20 (see arrow E) into chamber 97. Once again, a plunger, 103 is used to push (see arrow F) plug 101 through the sheath. Preferably, plug 101 should be long enough so that when fully discharged from the sheath (as depicted in Figure 21), it will fill substantially all of 25 channel 9, reaching almost to the surface of the skin.

When the front end of plug 101 reaches the end of *B* sheath ⁴⁵~~17~~ it abuts plug 93. Plunger 103 is then used to force about 1 cm. of plug 101 out of the sheath (107 30 on Figure 19). In this way, plug 101 takes over the function of holding plug 93 in place against puncture 13. While plunger 103 continues to hold plug 101 in *B* place (see arrow H), sheath ⁴⁵~~17~~ is withdrawn from channel 9 (see arrows G on Figure 20). As can be seen 35 *B* in Figure 22, when sheath ⁴⁵~~17~~ is fully withdrawn, plugs 93 and 101 fill substantially all of channel 9.

It is believed to be most desireable that the front plug 93 be of loosely packed material, while rear plug 101 be of a more densely packed material. Also, as presently contemplated, in its natural, unrestrained state, plug 101 has a cross section larger than that of cartridge 99. Therefore, in order to get it into the cartridge, it must be compressed. It then stays in this compressed state while in cartridge 99 as well as 5 ^{USA} while passing through sheath ^{15A}. However, after 10^B exiting from sheath ¹⁵ it naturally expands and presses against the walls of channel 9. The interaction then between plug 101 and the walls of channel 9 tends to hold the plug in place. As a result, very little if any external pressure is 15 required.

Accordingly, after only a very short period of time, perhaps almost immediately, the plunger can be removed, leaving only the two plugs in the wound (see Figure 20 21). Pressure on the artery (see arrows 105 in Figures 13-21) can then be released, permitting normal flow through the artery to resume.

Although it is not necessary, in the practice of the 25 method of the instant invention, for plugs 93 and 101 to fill all of channel 9 from artery to skin line, it is believed preferable that they do so. Alternatively, plug 101 can be made longer than necessary to reach the skin line, in which case it could then be cut off flush 30 with the skin. As yet another alternative, a single plug, the size of plugs 93 and 101 combined could be used instead of two separate plugs.

While it is believed most advantageous to remove the 35 procedure cannula and then insert a new sheath, it would be within the scope of the instant invention to

use the procedure cannula as the delivery sheath through which the hemostatic material is passed.

It should also be understood that the hemostatic material employed may take many forms. For example, it may be in the form of a liquid or it may have a more viscous paste-like consistency. When using liquid or paste-like materials, the delivery sheath, the hemostatic charge holder and the piston might most 10 advantageously be combined together in a single syringe-like device.

While the method and apparatus of this invention have been described in connection with several specific 15 embodiments, it should be understood that numerous modifications could be made by persons of skill in this art without departing from the scope of this invention. Accordingly, the above description is intended to be merely illustrative and not limiting. The scope of the 20 invention claimed should be understood as including all those alternatives and modifications which the above specification would readily suggest or which would readily occur or be apparent to one skilled in the art upon reading the above.
